Increased production of interleukin-10 in children with Down syndrome upon ex vivo stimulation with Streptococcus pneumoniae

Chantal J.M. Broers¹, Reinoud J.B.J. Gemke¹, Servaas A. Morré²,³, Michel E. Weijerman¹ and Anne Marceline van Furth⁴

BACKGROUND: Children with Down syndrome (DS) have an increased susceptibility to infections, due to altered humoral and/or cellular immunity. The aim of the study was to determine the cytokine production in whole blood of children with DS upon stimulation with heat-killed Streptococcus pneumoniae and lipopolysaccharide (LPS), in comparison with their healthy siblings.

METHODS: Whole blood of 61 children with DS and 57 of their healthy siblings was stimulated with 200 ng/ml LPS and 4 × 10⁷ colony-forming units/ml S. pneumoniae during 6, 24, and 48 h. Concentrations of pro- and anti-inflammatory cytokines, tumor necrosis factor (TNF)-α, interleukin (IL)-1β, IL-6, IL-8, IL-12p70, and IL-10 were determined at all time points.

RESULTS: Children with DS showed an increased IL-10 production upon stimulation with S. pneumoniae compared to their healthy siblings. At most time points, no significant differences were seen in cytokine production upon stimulation with LPS.

CONCLUSION: Children with DS may be prone to a severe course of pneumococcal pneumonia, because of an increased anti-inflammatory response.

RESULTS

Patients and Controls

After parental consent, 61 children with DS and 57 of their age-matched, healthy siblings were included in the study. In eight families, the child with DS was the only one to participate because there were no siblings. In 48 families, 1 sibling per child with DS participated. In five families, two siblings per child with DS participated. The average age (±SD) in the DS group was 7.8 (±5.1) vs. 9.3 (±5.5) y in the sibling group.

of pro- and anti-inflammatory cytokines (31). The specific immune response is initiated locally with the production thereby, further tissue invasion is prevented. Also, a more killing, the causing pathogen is destroyed and removed and and macrophages that are present locally. By phagocytosis and is mainly formed by the ciliated epithelium, dendritic cells, these pathogens, which is part of the innate immune response, microorganisms is present. The first line of defense against In the human respiratory tract, a continuous exposure to IL-10 levels were seen between the two groups.

Levels of Inflammatory Mediators
The levels of TNF-α, IL-1β, IL-6, IL-8, IL-10, and IL-12p70 in DS children and their healthy siblings upon stimulation with S. pneumoniae at 0, 6, 24, and 48 h are shown in Figure 1. IL-6 levels at 6 h were significantly higher in the DS group. IL-10 levels were significantly higher in the DS group than in the sibling group after 24 and 48 h. IL-12p70 levels at 6 h were significantly lower in the DS group. The levels of TNF-α, IL-1β, IL-6, IL-8, IL-10, and IL-12p70 in DS children and their healthy siblings upon stimulation with LPS at 0, 6, 24, and 48 h are shown in Figure 2. IL-1β levels at 48 h are significantly lower in the DS group. No significant differences in IL-10 levels were seen between the two groups.

DISCUSSION
In the human respiratory tract, a continuous exposure to microorganisms is present. The first line of defense against these pathogens, which is part of the innate immune response, is mainly formed by the ciliated epithelium, dendritic cells, and macrophages that are present locally. By phagocytosis and killing, the causing pathogen is destroyed and removed and thereby, further tissue invasion is prevented. Also, a more specific immune response is initiated locally with the production of pro- and anti-inflammatory cytokines (31). S. pneumoniae is an example of a Gram-positive bacteria and a frequent cause of community-acquired RTI (32). Young children are at risk for invasive pneumococcal disease because of the immaturity of their immune system. We wanted to investigate whether DS children can be considered as an additional risk group for pneumococcal RTI. Because we wanted to unravel the underlying innate immune response to a Gram-positive bacterial stimulus, we performed ex vivo whole-blood stimulation with S. pneumoniae in children with DS and their healthy siblings as a model for Gram-positive bacterial pneumonia. The most important finding of our study is that children with DS produce increased levels of IL-10 upon ex vivo stimulation with heat-killed S. pneumoniae. Many animal studies, especially in mice, have been performed investigating pulmonary S. pneumoniae infection. In mice with pneumonia induced by intranasal inoculation with S. pneumoniae, higher levels of the anti-inflammatory cytokine IL-10 were associated with decreased lung levels of TNF-α and interferon-γ, increased bacterial counts in lungs and blood, and early lethality (33). In our study, IL-10 levels increased significantly from 6 to 48 h in the DS group in comparison to the controls. In adults with pneumococcal pneumonia, high levels of IL-10 were present in serum at admission and declined within 48 h while treated with antibiotics (34). In another study in humans with pneumococcal pneumonia, higher levels of IL-10 increased the in-hospital mortality rate (35). Hence, the elevated IL-10 levels that we found in DS might be associated with a more severe course of S. pneumoniae pneumonia in DS but can be downregulated by the treatment with antibiotics. In the present study, we also found significantly higher IL-6 levels at 6 h in the DS group upon stimulation with S. pneumoniae. Van der Poll et al. (33) reported a protective effect of lung and plasma IL-6 in mice pneumonia after intranasal infection with S. pneumoniae; their mortality rate was less, and the amount of bacteria in the lungs was less than that in IL-6 knockout mice. In addition, higher levels of pro- and anti-inflammatory cytokines were present in the lung of the

(b) IL-1β levels. (c) IL-6 levels. (d) IL-8 levels. (e) IL-12p70 levels. (f) IL-10 levels. *P < 0.05; **P < 0.01; †P < 0.001; IL, interleukin; TNF, tumor necrosis factor.
IL-6 knockout mice. Hence, IL-6 downregulates the activation of the cytokine network in the lung, by controlling the activation of both agonist and antagonist mediators during pneumococcal pneumonia, and thus contributes to host defense (36). However, in humans with pneumococcal pneumonia, high levels of IL-6 in serum were associated with a more frequent admission to the intensive care unit and also a higher mortality (37,38). In complicated pneumococcal pneumonia with pleural effusion in children, increased release of proinflammatory cytokines such as TNF-α, IL-1β, and IL-6 in pleural fluid resulted in increased complications with the formation of fibrin deposition requiring surgical intervention (35,39). In our study, we did not find any differences in TNF-α and IL-1β in serum between DS children and the control group. However, IL-6 levels at 6 h were significantly elevated in these children. Since no studies have been performed in DS children with pneumococcal pneumonia which measure local cytokine production in the lung, it is difficult to extrapolate our results to the clinical perspective of this specific group of patients. On the one hand, the elevated IL-6 levels that we found in an early phase in DS children may protect against a severe clinical course of RTI when we have the mice experiments in mind; on the other hand, concerning the human studies as mentioned above, elevated IL-6 levels might have a deplorable effect.

In our study, we performed ex vivo whole-blood stimulation with LPS, a very important virulence factor of Gram-negative bacteria, in children with DS and their healthy siblings as a model for Gram-negative bacterial pneumonia. In a Gram-negative pneumonia model in mice, Herold et al. (40) showed that acute lung injury was mediated by IL-1β and was attenuated by an IL-1 receptor antagonist. In humans with Gram-negative nosocomial pneumonia, elevated concentrations of TNF-α and IL-6 were present in blood, but IL-1β was undetectable (41). High levels of IL-1β in bronchoalveolar lavage fluid of mechanically ventilated humans with a community-acquired pneumonia due to Pseudomonas aeruginosa were associated with a high bacterial load in the alveoli. This was also associated with progressive inflammation of the lung (42). Thus, the significantly lower levels of IL-1β at 48 h that we found in children with DS might protect them from acute lung injury in Gram-negative pneumonia. No significant differences in IL-10 levels were seen in these mice, as we found upon stimulation with S. pneumoniae.

Our results demonstrate that different microorganisms play an important role in the host response and trigger different inflammatory responses, depending on their intrinsic properties. Both pneumococci and LPS interact with TLR4 on innate immune cells, but in addition, pneumococci also interact with TLR1 and TLR2 on innate immune cells, which possibly leads to the difference in IL-10 production between the LPS and S. pneumoniae stimulations (43). The strength of our study is that, by choosing their age-matched siblings as a control group for the DS children, we minimized genetic, environmental, and age-related differences. The limitation of our study is that we have measured the systemic inflammatory response by measuring cytokine levels in the blood, which might not correlate with the cytokine levels in the pulmonary compartment during pneumonia. However, Kragsbjerg et al. (44) demonstrated high circulating levels of IL-8 in patients with community-acquired pneumonia caused by S. pneumoniae, and Bonten et al. (45) showed that high circulating levels of IL-6 and IL-8 were associated with higher mortality rates. Further studies are necessary to address these issues.

**Conclusion**

Children with DS show an increased IL-10 production in response to ex vivo stimulation with S. pneumoniae. This might result in a more severe course of pneumococcal disease in children with DS.
METHODS

Patients

The study was performed in the Vrije Universiteit Medical Center in Amsterdam, The Netherlands. The study protocol was approved by the Medical Ethics Committee of the Vrije Universiteit Medical Center. We invited 210 DS children from our Down syndrome outpatient clinic and their healthy siblings as controls to participate in the study. Inclusion criteria for children with DS were the following: DS diagnosis confirmed by chromosome analysis, age older than 3 mo, and no symptoms of infection at the time of blood sampling. Inclusion criteria for siblings (if present) were the following: age older than 3 mo and no symptoms of infection at the time of blood sampling. The age limit older than 3 mo was chosen because of possible technical difficulties to obtain enough blood for this study in very young children. Within one family, the age of the sibling was matched as much as possible with the age of the child with DS. The parents of participating children gave their written informed consent. From each child, 6 ml of heparinized blood was obtained by venipuncture. The blood samples were kept on ice while transporting to the laboratory.

Whole-Blood Stimulation With S. pneumoniae

Heat-killed S. pneumoniae (ATCC6303) was diluted in RPMI 1640 supplemented with glutamine (0.5 mmol/l) to a stock concentration of 4 × 10^7 colony-forming units/ml. For each time point, 250 µl of whole blood was incubated with 250 µl of the S. pneumoniae stock solution at 37 °C and 5% CO2; therefore, the concentration of stimulation was 4 × 10^7 colony-forming units/ml whole blood.

Whole-Blood Stimulation With LPS

LPS (from Escherichia coli O55:B5; Sigma-Aldrich, St Louis, MO) was diluted in RPMI 1640 supplemented with glutamine (0.5 mmol/l) to a stock concentration of 200 ng/ml. For each time point, 250 µl of whole blood was incubated with 250 µl of the LPS stock solution at 37 °C and 5% CO2; therefore, the concentration of stimulation was 200 ng/ml whole blood. The remaining whole blood at t = 0 and at 6, 24, and 48 h of incubation was centrifuged (48R centrifuge Hettich Rotina, Tuttinglen, Germany) for 10 min at 3,000 rpm at 4 °C, and the supernatant was stored at −80 °C until cytokine assays were performed.

Measurement of Plasma Inflammatory Mediators

TNF-α, IL-1β, IL-6, IL-8, and IL-10 were measured by cytometric bead array (Human Inflammation Kit, BD CBA; BD Biosciences, San Diego, CA), and IL-12p70 was measured by ELISA (Human IL-12(70) Kit, BD OptEIA; BD Biosciences, San Jose, CA) in accordance with the manufacturer’s recommendations.

Statistical Analysis

The categorical variables were analyzed by the χ² test. Cytokine data were analyzed by the Mann–Whitney U-test. Data are expressed as mean ± SEM. A P value of <0.05 was considered statistically significant.
